

OPG - Full View Dental X-Ray

The full view X-ray is needed to determine the impact of inflamed, toxic or bacterial influences on your gums and teeth, and their related consequences on your overall health.

As an example, Siphanospora germs can always be found in root-canals. Referred to as slow bacteria, this germ overloads your immune system, and the symptom of chronic inflammation ensues. Siphanospora germs are the same as those found in decaying or dying tissue. This means that wherever you have root-canals now, you previously had "living" dental pulp (with nerves, vessels, lymph tissue). In root-canal fillings this dental pulp is no longer nourished, resulting in tissue deterioration and death. This toxic condition spreads through-out the body, and negatively affects different body functions.

In addition, root-canal materials (including metal pivots) corrode and, over time, are reabsorbed into your body (despite claims to the contrary of those who produce these materials). For example, very toxic corrosion is often emitted from materials which contain copper. This toxin overloads your nervous, immune and hormone systems.

Furthermore the materials in root canals have an effect on other dental materials. They act as potent electrodes for the flow of current to amalgam or gold fillings. In the humid milieu of your mouth this current, which is easily measured, can be 1000 to 100'000 times stronger than normal nerve currents. This current is a constant irritation to your immune system, sympathetic nervous system and mucous membranes as well as nerves in your head. They can lead to neurological symptoms such as headache, migraine and neuralgias. The corrosion and currents are heavy loads on your body. For a short while a healthy body can compensate. However in severe illnesses, they should be removed as quickly as possible.

The full view X-ray is also taken to reveal hidden jaw bone irritation, such as ingrown wisdom-teeth. They interfere with the tooth related meridian system and lead to neurological and sympathetic nervous system disturbances. Jaw bone irritation can be seen from extracted teeth. This irritation can lead to very strong symptoms anywhere in your body and are seldom noticed at the point of irritation itself. Biological medicine methods seek to regulate these influences.

The close relationship of the teeth to the sinuses can explain chronic mucous membrane, sinus or lung disease. In addition, judging the mandibular articulation provides information about chewing dynamics, which, when disturbed, can lead to head and neck problems.

On the basis of this X-ray, we can determine the dental treatment required for the healing process of your disease.
